### ABSTRACT

As one of the 2D transition metal sulfides, 1T phase MoS<sub>2</sub> nanosheets (NSs) have been studied because of their distinguished conductivity and suitable electronic structure. Nevertheless, the active sites are limited to a small number of edge sites only, while the basal plane is catalytically inert. Herein, we report that boron (B) doped 1T phase MoS<sub>2</sub> NSs can replace precious metals as a co-catalyst to assist in photocatalytic H<sub>2</sub> production of 2D layered g-C<sub>3</sub>N<sub>4</sub> nanosheets (g-C<sub>3</sub>N<sub>4</sub> NSs). The H<sub>2</sub> evolution rate of prepared B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub> composites with 15 wt% B-MoS<sub>2</sub> (B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15, 1612.75 μmol h<sup>-1</sup> g<sup>-1</sup>) is 52.33 times of pure g-C<sub>3</sub>N<sub>4</sub> NSs (30.82 μmol h<sup>-1</sup> g<sup>-1</sup>). Furthermore, the apparent quantum efficiency (AQE) of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites under the light at λ = 370 nm is calculated and reaches 5.54%. The excellent photocatalytic performance of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites is attributed to the B ions doping inducing the distortion of 1T phase MoS<sub>2</sub> crystal, which can activate more base planes to offer more active sites for H<sub>2</sub> evolution reaction (HER). This work of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub> composites offers experience in the progress of effective and low-price photocatalysts for HER.

Recently, g-C<sub>3</sub>N<sub>4</sub> nanosheets (NSs) have attracted much attention to hydrogen production due to excellent chemical stability, suitable band structure, simple syntheses, low cost and special two-dimensional (2D) layered structure [1–3]. Besides, the special nitrogen-rich polymeric structure of 2D layered g-C<sub>3</sub>N<sub>4</sub> NSs could provide numerous active sites for HER [4,5]. Nevertheless, the photocatalytic hydrogen evolution performance of pure 2D layered g-C<sub>3</sub>N<sub>4</sub> NSs is unsatisfactory because of fast electron-holes pairs recombination and insufficient absorption of light [6–8]. Hence, it is essential to exploit novel methods to enhance the H<sub>2</sub> generation performance of 2D layered g-C<sub>3</sub>N<sub>4</sub> NSs. The construction of an internal electric field (IEF) is an effective strategy to enhance photocatalytic hydrogen evolution performance because of its key role in photo-induced carrier separation [9–11]. Precious metals act as cocatalysts is a common strategy to construct IEF [12,13]. Yet, the widespread application of precious metals is limited by high cost

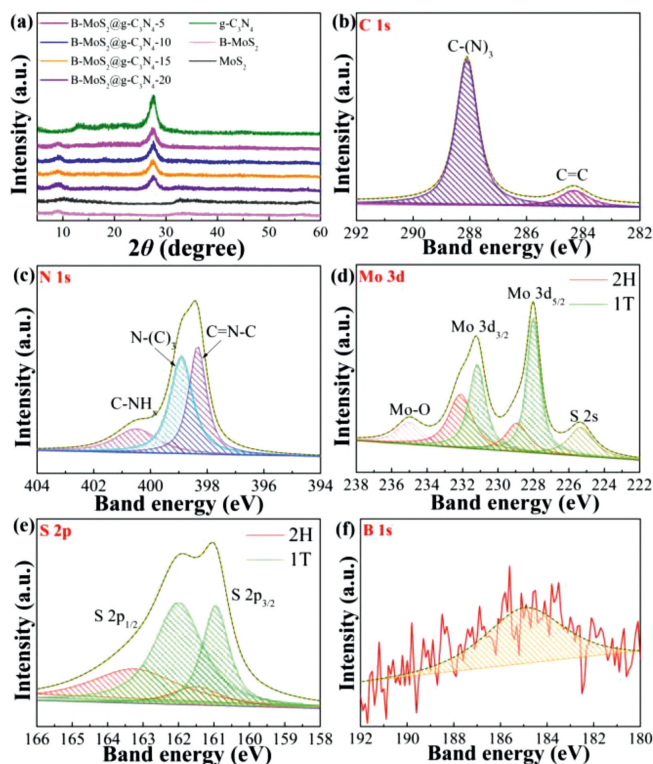

[14]. Hence, the development of an inexpensive and efficient cocatalyst is crucial for enhancing the photocatalytic activity of 2D layered g-C<sub>3</sub>N<sub>4</sub> NSs.

Among various cocatalysts, transition-metal chalcogenides, such as MoS<sub>2</sub>, receive widespread attention ascribed to the superior 2D layered structure [15–19]. MoS<sub>2</sub> has both semiconductor 2H phase and metallic 1T phase. Among them, metallic 1T phase MoS<sub>2</sub> NSs with octahedral coordination can improve the transfer and capture of photogenerated carriers to boost the photocatalytic H<sub>2</sub> evolution activity of 2D layered g-C<sub>3</sub>N<sub>4</sub> NSs, attributing to excellent conductivity [20–22]. In addition, the Gibbs free energy of 1T phase MoS<sub>2</sub> NSs for H<sup>+</sup> absorption is near-zero, which is suitable for HER [6,23]. However, the basal plane of MoS<sub>2</sub> NSs is inert, which limits the photocatalytic hydrogen evolution reaction [6]. Recent researches show that MoS<sub>2</sub>'s basal plane can be activated through doping atoms to design the active sites of MoS<sub>2</sub>, attributed to the local electronic structure modulation [6,24–26]. Thus, boron (B) ions are incorporated into the lattice of 1T phase MoS<sub>2</sub> could activate the basal plane, which can improve photocatalytic H<sub>2</sub> production performance. Hence, 2D-layered g-C<sub>3</sub>N<sub>4</sub> NSs modified by

<sup>1</sup> These authors contributed equally to this work.

**Fig. 1.** (a) X-ray diffraction patterns of pure  $g\text{-C}_3\text{N}_4$  NSs and  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$  composites. (b) C 1s, (c) N 1s, (d) Mo 3d, (e) S 2p and (f) B 1s XPS spectra of  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$ -15 composites.

doping B into 1T phase  $\text{MoS}_2$  NSs ( $\text{B-MoS}_2$  NSs) could exhibit better photocatalytic performance.

In this work, we propose  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$  composites for photocatalytic  $\text{H}_2$  evolution, in which triethanolamine acts as the sacrificial agent. The B into 1T phase  $\text{MoS}_2$  NSs are powerfully connected with 2D layered  $g\text{-C}_3\text{N}_4$  NSs through an easy hydrothermal method. The synthesized  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$  composites with 15 wt%  $\text{B-MoS}_2$  ( $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$ -15) display an efficient rate of hydrogen evolution ( $1612.75 \mu\text{mol h}^{-1} \text{g}^{-1}$ ), which is 52.33 times as much as pure  $g\text{-C}_3\text{N}_4$  NSs ( $30.82 \mu\text{mol h}^{-1} \text{g}^{-1}$ ). In addition, the apparent quantum efficiency (AQE) of pure  $g\text{-C}_3\text{N}_4$  NSs and  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$ -15 composites are 0.41 and 5.54% under the light at  $\lambda = 370 \text{ nm}$ . The loading of  $\text{B-MoS}_2$  NSs improves the light absorption of  $g\text{-C}_3\text{N}_4$  to stimulate more photogenerated carriers. In addition, the incorporation of B ions into the lattice of 1T phase  $\text{MoS}_2$  NSs can provide more active sites and speed up the photocatalytic hydrogen evolution reaction. Thus,  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$  composites display excellent photocatalytic  $\text{H}_2$  production activity.

The fabrication of  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$  composites is displayed in Scheme S1 (Supporting information). Firstly, pure  $g\text{-C}_3\text{N}_4$  NSs are synthesized via a direct thermal polymerization way of urea. During heating, urea first reacts to form bulk  $g\text{-C}_3\text{N}_4$  when the muffle furnace temperature is kept at  $550 \text{ }^\circ\text{C}$ , and then  $g\text{-C}_3\text{N}_4$  NSs with 2D layered structure are formed at the muffle furnace temperature of  $500 \text{ }^\circ\text{C}$ . Afterward,  $g\text{-C}_3\text{N}_4$  NSs, ammonium tetrathiomolybdate and boric acid are added to the 70 mL *N,N*-dimethylformamide solution and evenly dispersed. Then,  $\text{B-MoS}_2$  NSs are grown on the surface of  $g\text{-C}_3\text{N}_4$  NSs by hydrothermal method to obtain  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$  composites.

For pure  $g\text{-C}_3\text{N}_4$  NSs and  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$  composites, two characteristic peaks are located at  $13.1^\circ$  and  $27.4^\circ$  (green, pink, blue, yellow and purple curves in Fig. 1a), attributing to (100) and (002) planes of  $g\text{-C}_3\text{N}_4$  (JCPDS No. 87-1526) [27-29]. Simultane-

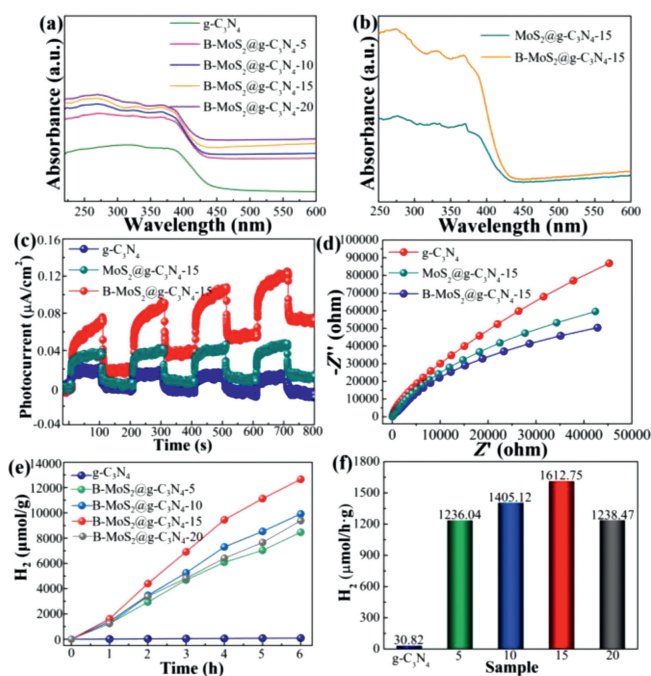

**Fig. 2.** SEM images of (a) pure  $g\text{-C}_3\text{N}_4$  NSs and (b)  $\text{B-MoS}_2$  NSs. (c) TEM and (d) HR-TEM images of  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$ -15 composites.

ously, the peaks at  $13.1^\circ$  (100) and  $27.4^\circ$  (002) of  $g\text{-C}_3\text{N}_4$  in  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$  composites become weaker after  $\text{B-MoS}_2$  NSs loading on  $g\text{-C}_3\text{N}_4$  NSs, attributing to the fact that the order degree of  $g\text{-C}_3\text{N}_4$  NSs is decreased by  $\text{B-MoS}_2$  NSs incorporation [6]. As shown in black curve in Fig. 1a, there are two peaks at  $10.2^\circ$  and  $32.5^\circ$  indexed to (002) and (100) plane of  $\text{MoS}_2$ . Compared with pure  $\text{MoS}_2$  (black curve in Fig. 1a), the peak at  $10.2^\circ$  of  $\text{MoS}_2$  shifts to a lower degree of  $8.8^\circ$  in contrast to the  $10.2^\circ$  (002) peak of  $\text{MoS}_2$  due to the B ions incorporating into the lattice of  $\text{MoS}_2$  cause the distortion of  $\text{MoS}_2$  crystal (red curve in Fig. 1a) [6]. In addition, the peak of  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$  composites at  $8.8^\circ$  is similar to  $\text{B-MoS}_2$ , indicating that  $\text{B-MoS}_2$  and  $g\text{-C}_3\text{N}_4$  coexist.

To further analyze the chemical bonding state, the XPS spectra of  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$  composites are tested. As shown in Fig. S1 (Supporting information), the survey XPS spectrum indicates that  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$  composites consist of C, N, Mo, S and B. As shown in Fig. 1b, the C 1s XPS spectrum is deconvoluted into two peaks at 284.8 and 288.4 eV, corresponding to  $\text{C}=\text{C}$  and  $\text{C}-(\text{N})_3$  bonds, respectively [30,31]. Fig. 1c indicates that the N 1s spectrum is deconvoluted into three peaks at 398.2, 399.1 and 400.6 eV, attributing to  $\text{C}=\text{N}-\text{C}$ ,  $\text{N}-(\text{C})_3$  and  $\text{C}-\text{NH}_x$ , respectively [32,33]. As shown in Fig. 1d, there are two green peaks at 227.8 and 230.9 eV, assigning to  $\text{Mo } 3d_{5/2}$  and  $\text{Mo } 3d_{3/2}$  of 1T phase [34]. The two pink peaks at 228.7 and 232.2 eV are attributed to  $\text{Mo } 3d_{5/2}$  and  $\text{Mo } 3d_{3/2}$  of 2H phase [34]. In addition, the peaks at 225.2 and 234.9 eV are assigned to S 2s and oxidation of Mo [6]. As for the S 2p XPS spectrum (Fig. 1e), two green peaks at 160.7 and 162.1 eV are attributed to  $\text{S } 2p_{3/2}$  and  $\text{S } 2p_{1/2}$  of 1T phase [35]. Simultaneously, there are two pink peaks at 161.5 and 163.4 eV, assigning to  $\text{S } 2p_{3/2}$  and  $\text{S } 2p_{1/2}$  of 2H phase [35]. Besides, according to Mo 3d and S 2p spectra, the proportion of 1T phase  $\text{MoS}_2$  is about 71.2%, indicating that 1T phase  $\text{MoS}_2$  in  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$  composites is the main phase. Fig. 1f exhibits a visible peak of B element at 184.6 eV, illustrating the successful doping of B ions in  $\text{MoS}_2$  [6]. Besides, the Raman spectrum of  $\text{B-MoS}_2$  (Fig. S2 in Supporting information) is measured to determine the  $\text{MoS}_2$  phase. There are three peaks at 147, 237, and  $335 \text{ cm}^{-1}$ , respectively, which correspond to the  $\text{J}_1$ ,  $\text{J}_2$ , and  $\text{J}_3$  modes of 1T phase  $\text{MoS}_2$  [16].

As shown in Fig. 2a,  $g\text{-C}_3\text{N}_4$  NSs display a special 2D layered structure, and the lamellae of  $g\text{-C}_3\text{N}_4$  NSs present irregular wrinkled sheet morphologies. Pure  $\text{B-MoS}_2$  displays flower-like assemblies composed of numerous small nanosheets (Fig. 2b). In Fig. 2c,  $\text{B-MoS}_2@g\text{-C}_3\text{N}_4$  composites still keep typical 2D sheet-shaped morphology. As shown in Fig. 2d,  $\text{B-MoS}_2$  NSs are assembled on the  $g\text{-C}_3\text{N}_4$  NSs, and the lattice space distance (0.98 nm) is attributed to the (002) plane of  $\text{MoS}_2$  [6]. The close connection be-

**Fig. 3.** (a) UV-vis DRS absorption spectra of g-C<sub>3</sub>N<sub>4</sub> NSs and B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub> composites. (b) UV-vis DRS absorption spectra of MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 and B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites. (c) Transient photocurrent responses. (d) EIS, (e) cumulated evolution and (f) photocatalytic H<sub>2</sub> production rates of the samples.

tween g-C<sub>3</sub>N<sub>4</sub> NSs and B-MoS<sub>2</sub> NSs facilitates the fast transfer of photogenerated electrons from g-C<sub>3</sub>N<sub>4</sub> NSs to B-MoS<sub>2</sub> NSs, which can effectively inhibit electron-hole pairs recombination. Fig. S3 (Supporting information) shows the EDX mapping images of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites, which display even distribution of C, N, Mo, S and B, indicating the coexistence of g-C<sub>3</sub>N<sub>4</sub> and B-MoS<sub>2</sub>.

As shown in Fig. 3a, an obvious absorption of g-C<sub>3</sub>N<sub>4</sub> NSs and B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub> composites is observed, and the absorption edge is ca. 430 nm. The band gap energy ( $E_g$ ) of pure g-C<sub>3</sub>N<sub>4</sub> NSs is obtained through the formula  $(\alpha h\nu)^{1/2} \propto h\nu - E_g$ , and the  $E_g$  of pure g-C<sub>3</sub>N<sub>4</sub> NSs is calculated and the value is 2.61 eV (Fig. S4 in Supporting information). Significantly, the optical absorption of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub> composites is stronger than that of pure g-C<sub>3</sub>N<sub>4</sub> NSs, which indicates that B-MoS<sub>2</sub> NSs loading onto g-C<sub>3</sub>N<sub>4</sub> NSs can effectively enhance the light absorption ability of the catalyst. Among these, the light absorption of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites is the strongest, which can boost the production of photogenerated carriers. To further research the role of B ions doping, the UV-vis DRS absorption spectra of MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 and B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites are shown in Fig. 3b. After B ions are doped in 1T-MoS<sub>2</sub> NSs, the light absorption of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites is improved (yellow curve in Fig. 3b), indicating that doping B into MoS<sub>2</sub> can boost the utilization of light.

To study the photogenerated charge separation and transfer properties of pure g-C<sub>3</sub>N<sub>4</sub> NSs, MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 and B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites, the photoelectrochemical (PEC) analysis is performed (Figs. 3c and d). Fig. 3c displays that pure g-C<sub>3</sub>N<sub>4</sub> NSs, MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 and B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites present the photocurrent responses on each illumination [6]. In addition, the photocurrent values of MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 and B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites are higher than that of pure g-C<sub>3</sub>N<sub>4</sub> NSs, which indicates that 1T-MoS<sub>2</sub> assembled on the g-C<sub>3</sub>N<sub>4</sub> NSs can effectively improve the generation and separation of photogenerated carriers. Notably, the photocurrent value of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites is superior to MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites, indicating that B ions doping could inhibit the recombination of electron-hole pairs. The

charge transfer activity of pure g-C<sub>3</sub>N<sub>4</sub> NSs, MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 and B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites is further explored through EIS measurement (Fig. 3d). MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 and B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites present a smaller arc radius than that of pure g-C<sub>3</sub>N<sub>4</sub> NSs, indicating 1T-MoS<sub>2</sub> can accelerate carrier separation (Fig. 3d). Besides, B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites display the smallest arc radius, indicating the separation of photoexcited carriers of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites is most effective. Hence, B ions doped into 1T-MoS<sub>2</sub> and MoS<sub>2</sub> NSs assembled on the g-C<sub>3</sub>N<sub>4</sub> NSs can synergistically promote photocatalytic activity.

To explore the possibility of hydrogen production, Mott-Schottky plots are tested to estimate the conduction band (CB) potential of pure g-C<sub>3</sub>N<sub>4</sub> NSs. As shown in Fig. S5 (Supporting information), g-C<sub>3</sub>N<sub>4</sub> is identified as an n-type semiconductor because of the positive slope of the curves in the Mott-Schottky plots. Through extrapolation to the x-intercept in Mott-Schottky plots, the flat band potential ( $E_{FB}$ ) of g-C<sub>3</sub>N<sub>4</sub> is obtained (-0.42 eV vs. Ag/AgCl). The obtained  $E_{FB}$  is converted to a potential vs. standard hydrogen electrode (NHE), and then the value is subtracted by 0.2 eV to obtain an  $E_{CB}$  vs. NHE of the sample. Therefore, the  $E_{CB}$  of g-C<sub>3</sub>N<sub>4</sub> is -0.4 eV vs. NHE. By the valence band potential ( $E_{VB}$ ) =  $E_g + E_{CB}$  and  $E_g$  results (Fig. S4 in Supporting information), the  $E_{VB}$  of g-C<sub>3</sub>N<sub>4</sub> is 2.21 eV vs. NHE (Fig. S6 in Supporting information). Based on the above research, the  $E_{CB}$  of as-prepared g-C<sub>3</sub>N<sub>4</sub> NSs is lower than 0 eV, which indicates that prepared g-C<sub>3</sub>N<sub>4</sub> NSs can conduct photocatalytic hydrogen production.

Fig. 3e indicates that the photocatalytic hydrogen production of all photocatalysts is linear with time, indicating that the catalyst has stable photocatalytic H<sub>2</sub> evolution performance. As shown in Fig. 3f, bare g-C<sub>3</sub>N<sub>4</sub> shows an unacceptable photocatalytic hydrogen evolution performance (30.82 μmol h<sup>-1</sup> g<sup>-1</sup>), which is attributed to the fast recombination of carriers and low light utilization. Yet, B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites present excellent photocatalytic hydrogen production and H<sub>2</sub> evolution rate, indicating that adding B-MoS<sub>2</sub> NSs as cocatalysts can promote the photocatalytic activity of catalysts. The H<sub>2</sub> evolution rate of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites (1612.75 μmol h<sup>-1</sup> g<sup>-1</sup>) is 52.33, 1.3, 1.15 and 1.31 times of bare g-C<sub>3</sub>N<sub>4</sub> NSs (30.82 μmol h<sup>-1</sup> g<sup>-1</sup>), B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-5 (1236.04 μmol h<sup>-1</sup> g<sup>-1</sup>), B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-10 (1405.12 μmol h<sup>-1</sup> g<sup>-1</sup>), B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-20 composites (1238.47 μmol h<sup>-1</sup> g<sup>-1</sup>), respectively. The improved photocatalytic HER performance of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub> composites indicates that B-MoS<sub>2</sub> cocatalyst loading onto g-C<sub>3</sub>N<sub>4</sub> improves the utilization of light to stimulate more photogenerated electrons, accelerates carrier separation, and inhibits electron-hole pairs recombination. However, increasing B-MoS<sub>2</sub> NSs content from 15% to 20%, a decrease in photocatalytic performance is detected, owing to the overmuch B-MoS<sub>2</sub> NSs loading on g-C<sub>3</sub>N<sub>4</sub> NSs impediment the photo-absorption of g-C<sub>3</sub>N<sub>4</sub> NSs. As shown in Fig. S7 (Supporting information), the photocurrent values of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites is higher than that of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-20 composites, which indicates that the overmuch B-MoS<sub>2</sub> NSs loading on g-C<sub>3</sub>N<sub>4</sub> NSs in B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-20 is adverse for the photocatalytic performance of photocatalyst. To study the effect of B ions doping, we measure the hydrogen production of MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites. As shown in Fig. S8 (Supporting information), the photocatalytic hydrogen production amount and rate of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites (1612.75 μmol h<sup>-1</sup> g<sup>-1</sup>) is higher than that of MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites (1370.68 μmol h<sup>-1</sup> g<sup>-1</sup>), attributing that B ions doping into MoS<sub>2</sub> can activate the base planes of MoS<sub>2</sub> and offer more active sites. To further evaluate the H<sub>2</sub> production cycle property of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites, the photocatalytic H<sub>2</sub> evolution performance is tested for 15 h (Fig. S9 in Supporting information). Almost 92.4% of the incipient property is kept, and the micromorphology of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites after the cycle test (Fig. S10 in Supporting information) does not change

**Scheme 1.** Schematic illustration of the photocatalytic H<sub>2</sub> evolution mechanism of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub> composites.

significantly, indicating the good stability of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites. We further determine the apparent quantum efficiency (AQE) of pure g-C<sub>3</sub>N<sub>4</sub> NSs and B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites under light at  $\lambda = 370$  nm irradiation. As shown in Fig. S11 (Supporting information), the AQE value of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites (5.54%) is higher than that of bare g-C<sub>3</sub>N<sub>4</sub> NSs (0.41%), which illustrates the optical utilization of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites is higher than that of pure g-C<sub>3</sub>N<sub>4</sub> NSs.

According to the above studies, we propose a possible photocatalytic hydrogen evolution mechanism to explicate the reason for the improved photocatalytic hydrogen evolution performance of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub> composites (Scheme 1). The loading of B-MoS<sub>2</sub> NSs improves the light absorption of g-C<sub>3</sub>N<sub>4</sub> to stimulate more photo-generated carriers and offer more active sites for HER. In addition, B-MoS<sub>2</sub> as a cocatalyst can capture photoinduced electrons, accelerate electron transfer and inhibit recombination of electron-hole pairs. B ions are doped into the lattice of 1T-MoS<sub>2</sub>, which can activate more base planes of 1T-MoS<sub>2</sub> and is suitable for the HER to activate H<sup>+</sup>. The photoexcited electrons produced under the sunlight through g-C<sub>3</sub>N<sub>4</sub> moved to B-MoS<sub>2</sub>, and then reduced water to hydrogen. Concurrently, TEOA as a sacrificial agent consumed the holes. Hence, the close combination of B-MoS<sub>2</sub> and g-C<sub>3</sub>N<sub>4</sub> boosts the photocatalytic hydrogen evolution activity of photocatalysts.

In conclusion, we have successfully synthesized an efficient B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub> composite for photocatalytic H<sub>2</sub> evolution via cocatalyst and doping strategy. The as-prepared B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub> composites with 15 wt% B-MoS<sub>2</sub> (B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15) present an extremely improved photocatalytic H<sub>2</sub> evolution rate of 1612.75  $\mu\text{mol h}^{-1} \text{g}^{-1}$ , which is 52.33 times of bare g-C<sub>3</sub>N<sub>4</sub> NSs (30.82  $\mu\text{mol h}^{-1} \text{g}^{-1}$ ). The above experimental results confirm that the enhanced photocatalytic activity of B-MoS<sub>2</sub>@g-C<sub>3</sub>N<sub>4</sub>-15 composites may be assigned to the following factors: (1) As a cocatalyst, B doped 1T phase MoS<sub>2</sub> NSs greatly improves the light utilization of photocatalyst and stimulates more photogenerated carriers; (2) B-MoS<sub>2</sub> NSs with excellent conductivity are closely connected onto g-C<sub>3</sub>N<sub>4</sub> NSs, which can accelerate electron transfer and inhibit carrier recombination; (3) The base planes are activated through doping B ions into the lattice of MoS<sub>2</sub>, which can induce the distortion of MoS<sub>2</sub> crystal and provide more active sites for HER. This easy assembly strategy offers guidance for rationally constructed

photocatalysts based on B-doped 1T phase MoS<sub>2</sub> as a cocatalyst for H<sub>2</sub> production.
